Intonational PERiods (IPE) and Formulaic Language: 
A Genre-based Analysis of a French Speech Database

Maria Zimina and Nicolas Ballier

Abstract. This paper addresses prosodic aspects of phraseology from the point of view of the ‘lexicogrammar’ approach in Rhapso\-die, a richly annotated corpus of spoken French. Textometric methods enable the selection of statistically relevant phenomena both in terms of marked prosodic salience and recurrent lexicogrammatical features. Among the possible prosodic characteristics of phraseology, salient initial prominences of prosodic macro-units are considered in this paper. Within the Rhapso\-die annotation framework, these macro-units correspond to the largest prosodic constituents, the Intonational PERiods (IPE). We have analysed the IPEs bearing the strongest level of initial prosodic salience. The prosodic properties of the units so delineated are discussed, as well as the discourse type of these phenomena. Some recurrent patterns of oratory and procedural speech genres are described using prosody and Part-of-Speech (POS) annotations. We suggest that the role of initial salience of specific prosodic patterns is to facilitate perception and interaction in human speech and to establish the structure of speakers’ turns.

Keywords: Lexicogrammar, Prosodic Constituents, Salience, Textometrics

1 Introduction

1.1 Phraseology and Prosody

Our research examines the notions of phraseology and formulaic language in the process of speech production. The terms “phraseology” and “formulaic language” will be discussed in this paper from the point of view of the ‘lexicogrammar’ approach [5]. From this perspective, our objects of study are predictable and productive sequences of signs called lexicogrammatical patterns (lexical signs, grammatical constructions). Composed of permanent ‘pivotal’ signs and a more productive ‘paradigm’, these patterns may be discontinuous and may or may not be syntactic constituents. In contrast with the lexicological approach to phraseology, which studies phraseological phenomena in terms of a continuum ranging from ‘free combinations’ to ‘fixed phrases’, the ‘lexicogrammar’ approach is particularly suited to identifying extended patterns within a particular register or genre [ibid.]. We aim to explore the ways in which prosodic features may correlate with extended lexical patterns, as well as the extent to
which prosody corresponds to patterns which have a particular register or discourse function.

Recent studies have shown that prosodic features extracted from speech databases can be successfully integrated into the investigation of phraseology [16] and its pedagogical applications [1]. Prosody is key to fluency in speech production and reception [ibid.]. Most transcriptions of prosody indicate specific events in speech: boundary tones, pitch accents, disfluent segments, etc. [21]. These speech events coded in spoken corpora are possible candidates for identifying the prosodic characteristics of formulaic language [7] [20].

In this respect, a quantitative analysis of finely annotated spoken corpora facilitates research on the prosodic aspects of phraseology: “If most of the formulaic expressions we know have been acquired from and are used in speech, the phonological representation of formulaic expressions should, in theory, play a fundamental role in the lexical storage and retrieval.” [16]. Unfortunately, large spoken corpora are rarely distributed with a fine-grained prosodic annotation.

For French, a free reference corpus, the *Rhapsodie* speech database (ANR Rhapsodie 07 Corp-030-01), is now available [17]. This syntactic and prosodic treebank is composed of 57 short samples of spoken French (approximately 5 minutes long), orthographically and phonetically transcribed (approximately 33,000 words). This corpus was designed to investigate the prosody/syntax/discourse interface across several discourse types and speaking styles (oratory, narrative, description, argumentation, procedural; interactive, public and private; semi-interactive and non-interactive; planned, spontaneous and semi-spontaneous, etc.) [11]. The resource can be downloaded from www.projet-rhapsodie.fr.

1.2 A Summary of the Rhapsodie Methodology for Prosodic Annotation

The *Rhapsodie* project follows a bottom-up approach driven by the data [10]. The transcriptions and the annotations are aligned on the speech signal and *Praat* Textgrids [2] are available online [17]. The prosodic annotation is based on the assumption that, out of the total acoustic signal, only certain perceptual cues selected by the listener are relevant for linguistic communication [10]. Following this assumption, 10 research teams collaborated on the following workflow:¹ (1) Manual annotation of relevant perceptual prosodic events. (2) Automatic characterization of the prosodic constituents based on this manual annotation. (3) Automatic stylization of melodic contours and annotation of tones associated with the prosodic constituents.

This combination of manual and automated annotations allowed a segmentation of speech into prosodic periods [12], which relies on the initial characterization of two types of speech events retained from the manual annotation: prosodic prominence and disfluencies. For illustration purposes, Fig. 1 gives a summary of this prosodic structure [10]. It is organized around rhythmic and melodic components. The hierarchy of constituents includes:

1. Intonational PEriods (IPE)
2. Intonational PAckages (IPA): sub-constituents internal to periods
3. Rhythmic Groups (RG): sub-constituents internal to intonational packages
4. Metrical Feet (MF): sub-constituents inside rhythmic groups
5. Syllables, with Prominence levels, including: 0 (non-prominent), W (weak) and S (strong).

Fig. 1. Prosodic structure of the Rhapsodie speech database corpus [10]

The speech dataset annotated within this perception-driven prosodic annotation opens up new possibilities for the investigation of phraseology. As the link between the “marked status” as a +phrase/expression/formulaic expression etc. and prosodic constituents is still to be revealed, some of our research questions are of an exploratory nature and more than 60 layers of morpho-syntactic, syntactic, macro-syntactic and prosodic annotation in Rhapsodie necessarily open new perspectives for the exploration of the prosodic dimension of phraseology. We have decided to focus on the initial structure of IPE macro-units and on the contribution of recurrent patterns of initial prosodic salience to the perception of formulaic language. Previous research has considered various candidates for specific prosodic contours (sometimes called ‘melodic clichés’ [9]) in the phraseology of spoken discourse [3] [16]. Our quantitative approach focuses on the recurrent prominences observable after speech breaks.

2 Exploring Linguistic Fixedness in French on the Basis of Prosodic Features

2.1 Textometric Procedures

The segmentation of the Rhapsodie speech data into IPE considers melodic variations in time and silent pauses used, regardless of segmental and syntactic constraints [10]. Following our work on the analysis of lexicogrammatical patterns in written texts [6], our study explores the prosody/lexicogrammar interface. In order to discover regular patterns, we conduct a textometric analysis of repeated POS segments in relation to IPE boundaries. At this stage, the goal is to isolate a set of linguistic regularities associated with what is commonly perceived as a strong prosodic boundary [10]. Computation of characteristic elements [14], which comes after the first stage, aims to describe perceived regularities with respect to genre and speaking styles, categorized in Rhapsodie as ‘subgenres’ (see Figure 2 below) [17] [10].

Typically, a hypergeometric model [15] is the statistical rationale for the computation of indices signaling characteristic POS or POS repetitions within each of the
corpus parts (interactive/non-interactive/semi-interactive speech, dialogue / monologue, subgenre, etc.). The computation adapts classical statistical tests [14] that can detect, within each of the parts of a corpus, which elements are used frequently as well as the ones which tend to be rarely used. As a consequence, characteristic elements discovered in this second stage allow for the investigation of candidate formulae in the breaking of the speech flow across different social contexts. Different variables can be analyzed within this approach using textometric software.

2.2 Le Trameur Software

The software used in our study is *Le Trameur* [13]. It allows for the intersecting analysis of multiple speech and text annotation layers in various forms of textometric analysis. For example, more than 60 annotations are used in *Rhapsodie*. They are all displayed and processed in a single graphical user interface [4]. *Le Trameur* can be used to automatically re-annotate the dataset and potentially add new annotation layers. Moreover, the researcher can select and manually correct any occurrence of a given tag of the dataset. Various textometric analyses available using this software have allowed us to compare the specific lexicogrammatical regularities of IPE characteristics in several communicative situations. We used frequent characteristic patterns detected as “starters” of the main prosodic constituents to detect formulaic expressions in different speech contexts. The following section illustrates some of the first findings resulting from our experiments with the *Rhapsodie* corpus.

3 Characteristic POS Patterns at the Beginning of the IPE in Several Speech Genres of Rhapsodie

3.1 Detection of Salient POS and POS Patterns

<table>
<thead>
<tr>
<th>POS list</th>
<th>Strongest initial prosodic salience</th>
<th>Total of the POS (any position)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Cl (Clitic pronoun)</td>
<td>511 occ.</td>
<td>4,179 occ.</td>
</tr>
<tr>
<td>2. J (Coordinating conjunction)</td>
<td>443 occ.</td>
<td>1,142 occ.</td>
</tr>
<tr>
<td>3. I (Interjection)</td>
<td>439 occ.</td>
<td>1,984 occ.</td>
</tr>
<tr>
<td>5. Pre (Preposition)</td>
<td>238 occ.</td>
<td>3,443 occ.</td>
</tr>
<tr>
<td>6. D (Determiner)</td>
<td>209 occ.</td>
<td>4,080 occ.</td>
</tr>
<tr>
<td>7. V (Verb)</td>
<td>112 occ.</td>
<td>5,994 occ.</td>
</tr>
<tr>
<td>8. Qu (Relative pronoun)</td>
<td>97 occ.</td>
<td>799 occ.</td>
</tr>
<tr>
<td>9. CS (Subordinating conjunction)</td>
<td>74 occ.</td>
<td>729 occ.</td>
</tr>
<tr>
<td>10. N (Noun)</td>
<td>65 occ.</td>
<td>6,317 occ.</td>
</tr>
</tbody>
</table>
In decreasing order of frequency, clitic pronouns, coordinating conjunctions, interjections, adverbs, prepositions, determiners, verbs, relative pronouns, subordinating conjunctions and nouns are the most frequent POS categories (resulting from morphosyntactic tagging with SEM [19]) that occur at the beginning of the IPE (Freq>50), see Table 1 above.

Repeated segments computation [18] is further used to study the specific attractions of these POS categories at the beginning of the IPE contexts. Table 2 presents the most frequent POS recurrences (Freq>50) in the IPE initial position.

Table 2. The most frequent POS recurrences (POS N-grams) in the IPE initial position

<table>
<thead>
<tr>

</tr>
<tr>
<td>9. I + I</td>
<td>60 occ.</td>
<td>258 occ.</td>
</tr>
</tbody>
</table>

3.2 Characteristic Elements in Different Speech Contexts

Characteristic elements [15] describe parts of the corpus displaying these POS repetitions that are significantly more salient or a great deal less salient in a given part of the corpus than in the overall corpus. For example, it is clear from the graphs on Fig. 2 that Cl + V is a positive characteristic element at the beginning of the IPE in the speech contexts of oratory genre (specificity indice: +10). The following examples reveal some lexicogrammatical realizations of this productive pattern in Rhapsodie (categories corresponding to CL + V are in bold in the following examples):

- Oratory genre: IPE starting with Cl + V (rhetorical function: performatives)
  - # je suis heureux de me retrouver ce soir #
  - # elle salue la loyauté #
  - # il faut les faire grandir #
  - # je souhaite que l'Europe #
Another strong characteristic pattern of this genre is D + N (specificity: +26):

- Oratory genre: IPE starting with D + N (rhetorical function: theme-selection)
  
  ─ # la démocratie politique et sociale #
  ─ # la France sera ce que nous voudrons qu'elle soit # une nation unie #
  ─ # le droit de grève # le droit à l'instruction #
  ─ # un moment fort #
  ─ # l'exigence de solidarité #

Cl + V is also revealed as a positive characteristic element of initial prosodic salience (specificity: +6) in the procedural speech contexts:

- Procedural genre: IPE starting with Cl + V (rhetorical function: instructions)
  
  ─ # on passe devant le le kiosque à journaux #
  ─ # tu vas tout droit #
  ─ # vous continuez # vous prenez le rond-point tout droit #
  ─ # on traverse la rue #
  ─ # tu descends toute la pente #

Coordinating conjunction (J) is a characteristic element of initial salience in procedural speech. It is present in three characteristic patterns: J + I (specificity: +5), J + CL (specificity: +3), J + Adv (specificity: +3):

- Procedural genre: IPE starting with J + I/CL/Adv (instructions, hesitation)
  
  ─ # et vous allez toujours tout droit #
  ─ # et vous suivez toujours la ligne du tram #
  ─ # et euh donc je vais jusqu’au & jusqu’à la place Victor Hugo #
  ─ # et là je me retrouve euh en effet euh s- près des rails du tram #
  ─ # et euh et ben voilà j'arrive au niveau de la grande place de la gare où … #

4 The Role of Formulaic Expressions in the Organization of Speech

Our findings can be summed up as a set of observational statements:

1. Speech boundaries of intonational periods (IPE) can be easily related to the characteristic repetitions of lexico-grammatical patterns revealed by POS recurrences at the beginning of the IPE. This prosodic salience of recurrent initial left-aligned patterns is a valuable property which can be used to explore how prosody is related to formulaic language. For example, in the French reference corpus, intonational periods tend to begin with specific POS categories, the most frequent ones being clitic pronouns, coordinating conjunctions, interjections, adverbs, prepositions, determiners and verbs. These results are to be compared with other available speech corpora data in French.
2. The initial IPEs vary in different social contexts and reflect specific communicative needs of the speakers. However, the pivotal elements of these productive patterns, such as the expression of predicates CL+V, have stable lexico-grammatical realizations in the Rhapsodie speech dataset (“je salue”, “elle souhaite”, “il faut”, “on continue”, etc.). These elements are regularly reproduced in specific linguistic contexts and reflect regular rhetorical units (performatives, theme-selection, instructions etc.) with predictable/definable discourse functions.

3. The linguistic characteristics of these salient contexts and their degree of semantic unity are quite different. For example, the illocutionary unit § # on passe devant le kiosque à journaux # shows a possible extension of the pivotal element “on passe” in a specific communicative situation, while # un moment fort # has a greater semantic unity. More experiments with the Rhapsodie dataset are necessary to explore the precise nature of these phenomena using other annotation levels.

5 Future Work

One of the interesting outputs of this study is that it paves the way for a new investigation on inter-annotator agreement in prosodic processing. As manual annotation is
part of prosodic segmentation in Rhapsodie, future experiments could consider constraints of memory \[8\] and processing capabilities of the annotators in determining IPE boundaries when it comes to formulaic language. However, we are convinced that for the present study of the phraseology/prosody interactions, the specificities of the Rhapsodie speech database are valuable inputs.

6 Conclusion

Prosodic segmentation into intonational periods offers new insights for the observation of the functions of formulaic expressions in speech. A possible place to start with is the identification of annotated IPE boundaries and their correspondence with frequent morpho-syntactic repetitions. In this respect, characteristic POS repetitions at the beginning of intonation periods are more than simply recurrent groups of linguistic units. In our opinion, they represent an observational tool that can be used to investigate how prosodic variations depending upon several factors (interactional need, social context, genres, etc.) are related to formulaic language.

The experiments proposed in our study represent an attempt to account for the uses of these specific patterns after prosodic breaks where the speakers are likely to rely upon the formulaic language for specific communication purposes. A possible interpretation of these prosodic features naturally comes from the analysis of different speech contexts where the initial salience of specific prosodic phraseology facilitates speech perception. In this respect, recurrent patterns are likely to reflect strong speech signals to which speakers and listeners respond in a distinct way, showing an important influence of intrinsic experience of language acquisition in the structuring of speaker and listener interaction, speakers’ turns, etc. This type of analysis can be further extended to include all the other prosodic characteristics (tone, pause length, etc.) available in the Rhapsodie speech dataset.
